## **Revealing Majorana bound states properties with electronic transport in three terminal devices**

**Dr. Thibaut Jonckheere**

Aix Marseille Univ, Université de Toulon, CNRS, CPT, Marseille

**Date: June 7 (Fri), 2019**

**Time: 15:00-16:30**

**Place: Room 401, Science Bldg. 5, Kyoto University**

### **Abstract:**

Majorana bound states are quasiparticles with exceptional properties, which should appear at the boundaries of one-dimensional topological superconductors wires. The clear-cut experimental identification of these Majorana bound states in transport measurements still poses experimental challenges. In this talk, I will show that using three terminal devices out-of-equilibrium, and measuring transport properties like current and noise allow to get original signature demonstrating the Majorana bound states properties. I will first consider a junction where a topological superconductor (TS) wire is connected to two biased normal leads, and show that the sign of the current correlations is directly related to the presence of a Majorana bound state. Then I will consider a similar junction made of three TS wires. There I will show that the effective zero-energy Majorana state formed at the junction of the three TS wires is directly responsible for giant shot noise amplitudes, in particular at low voltages and for small contact transparency.
